### Lecture 14: Semantic Role Labeling

#### Frank Keller

School of Informatics University of Edinburgh keller@inf.ed.ac.uk

March 14, 2017

- Introduction
  - Semantic Role Labeling
  - Proposition Bank
  - Pipeline and Features
- 2 Semantic Role Labeling with Neural Networks
  - Architecture
  - Features and Training
  - Results

Reading: Zhou and Xu (2015).

Background: Jurafsky and Martin (2016: Ch. 22).

Earlier in this course we looked at *parsing* as a fundamental task in NLP. But what is parsing actually good for?

Earlier in this course we looked at *parsing* as a fundamental task in NLP. But what is parsing actually good for?

Parsing is used to break up sentences into meaningful parts, which can then feed into *downstream semantic tasks*:

- semantic role labeling (figure out who did what do whom);
- semantic parsing (turn a sentence into a logical form);
- word sense disambiguation (figure out what the words in a sentence mean);
- compositional semantics (compute the meaning of a sentence based on the meaning of its parts).

Earlier in this course we looked at *parsing* as a fundamental task in NLP. But what is parsing actually good for?

Parsing is used to break up sentences into meaningful parts, which can then feed into *downstream semantic tasks*:

- semantic role labeling (figure out who did what do whom);
- semantic parsing (turn a sentence into a logical form);
- word sense disambiguation (figure out what the words in a sentence mean);
- compositional semantics (compute the meaning of a sentence based on the meaning of its parts).

In this lecture, we will look at *semantic role labeling* (SRL).

#### Frame Semantics

- due to Fillmore (1976);
- a frame describes a prototypical situation;
- it is evoked by a frame evoking element (predicate);
- it can have several frame elements (arguments; sem. roles).

#### Frame Semantics

#### Frame Semantics

- due to Fillmore (1976);
- a frame describes a prototypical situation;
- it is evoked by a frame evoking element (predicate);
- it can have several frame elements (arguments; sem. roles).

### Properties of Frame Semantics

- provides a shallow semantic analysis (no modality, scope);
- granularity in between "universal" and "verb specific" roles;
- generalizes well across languages;
- can benefit various NLP applications (IR, QA).

#### Properties of Frame Semantics

# Proposition Bank

PropBank is a version of the Penn Treebank annotated with semantic roles. More coarse-grained than Frame Semantics:

```
Arg0 proto-agent
Arg1 proto-patient
Arg2 benefactive, instrument, attribute, end state
Arg3 start point, benefactive, instrument, or attribute
Arg4 end point
ArgM modifier (TMP, LOC, DIR, MNR, etc.)
```

Arg2-Arg4 are often verb specific.

# PropBank Corpus

### Example (from Jurafsky and Martin 2016):

(1) increase.01 "go up incrementally"

Arg0: causer of increase

Arg1: thing increasing

Arg2: amount increased by, EXT, or MNR

Arg3: start point

Arg4: end point

- (2) [Arg0 Big Fruit Co.] increased [Arg1 the price of bananas].
- (3) [Arg1 The price of bananas] was increased again [Arg0 by Big Fruit Co.]
- (4) [Arg1 The price of bananas] increased [Arg2 5%].

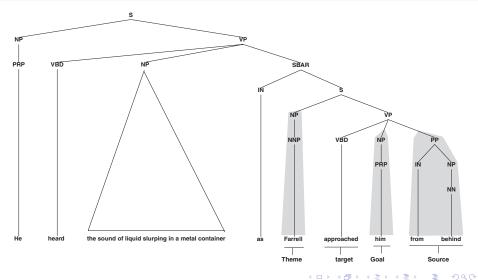

# The SRL Pipeline

The SRL task is typically broken down into a sequence of sub-tasks (e.g., Gildea and Jurafsky 2002):

- parse the training corpus;
- 2 match frame elements to constituents;
- extract features from the parse tree;
- train a probabilistic model on the features.

More recent SRL systems use dependency parsing, but follow the same pipeline architecture.

## Match Frame Elements

Natural Language Understanding

## Extract Parse Features

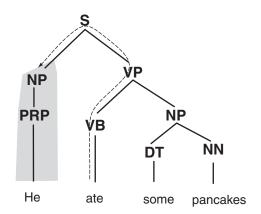

Assume the sentences are parsed, then the following features can be extracted for role labeling (Gildea and Jurafsky 2002):

- Phrase Type: syntactic type of the phrase expressing the semantic role (e.g., NP, VP, S);
- Governing Category: syntactic type of the phrase governing the semantic role (NP, VP), only used for NPs;
- Parse Tree Path: path through the parse tree from the target word to the phrase expressing the role;
- Position: whether the constituent occurs before or after the predicate; useful for incorrect parses;
- Voice: active or passive; use heuristics to identify passives;
- Head Word: the lexical head of the constituent.

#### Extract Parse Features

Path from target ate to frame element  $He: VB\uparrow VP\uparrow S\downarrow NP$ 

# Semantic Role Labeling with Neural Networks

SRL is a sequence labeling task. We should therefore be able to use recurrent neural networks (RNNs or LSTMs) for it.

In this lecture, we will discuss the end-to-end SRL system of Zhou and Xu (2015) using a *deep bi-directional LSTM (DB-LSTM)*:

Zhou and Xu's (2015) approach:

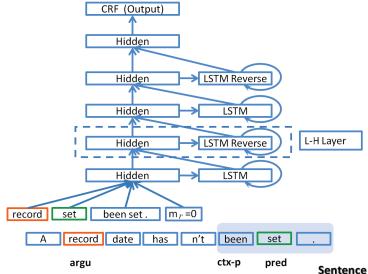

- uses no explicit syntactic information;
- requires no separate frame element matching step;
- needs no expert-designed, language-specific features;
- outperforms previous approaches using feedforward nets.

#### Architecture

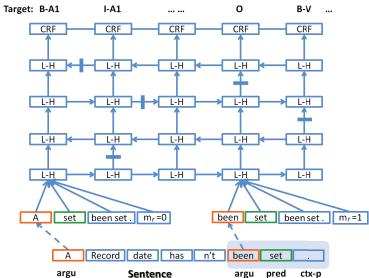

The DB-LSTM is an two-fold extension of the standard LSTM:

- a bidirectional LSTM normally contains two hidden layers, both connected to the same input and output layer, processing the same sequence in opposite directions;
- here, the bidirectional LSTM is used differently:
  - a standard LSTM layer processes the input in forward direction;
  - the output of this LSTM layer is the input to another LSTM layer, but in reverse direction;
- these LSTM layer pairs are stacked to obtain a deep model.

### Architecture

## Architecture: Unfolded

#### **Features**

The input is processed word by word. The input features are:

- argument and predicate: the argument is the word being processed, the predicate is the word it depends on;
- predicate context (ctx-p): the words around the predicate; also used to distinguish multiple instances of the same predicate;
- region mark  $(m_r)$ : indicates if the argument is in the predicate context region or not;
- if a sequence has  $n_p$  predicates it is processed  $n_p$  times.

Output: semantic role label for the predicate/argument pair using IOB tags (inside, outside, beginning).

#### **Features**

An example sequence with the four input features: argument, predicate, predicate context (ctx-p), region mark  $(m_r)$ :

Time	Argument	Predicate	ctx-p	$m_r$	Label
1	А	set	been set .	0	B-A1
2	record	set	been set .	0	I-A1
3	date	set	been set .	0	I-A1
4	has	set	been set .	0	0
5	n't	set	been set .	0	B-AM-NEG
6	been	set	been set .	1	0
7	set	set	been set .	1	B-V
8		set	been set .	1	0

# **Training**

- Word embeddings are used as input, not raw words;
- the embeddings for arguments, predicate, and ctx-p, as well as  $m_r$  are concatenated and used as input for the DB-LSTM;
- eight bidirectional layers are used;
- the output is passed through a conditional random field (CRF); allows to model dependencies between output labels;
- the model is trained with standard backprop using stochastic gradient descent;
- fancy footwork with learning rate required to make this work;
- Viterbi decoding is used to compute the best output sequence.

# Experimental Setup

- Train and test on CoNLL-2005 dataset (essentially a dependency parsed version of PropBank);
- word embeddings either randomly initialized or pretrained;
- pretrained embeddings used Bengio's Neural Language Model on English Wikipedia (995M words);
- vocabulary size 4.9M; embedding dimensionality 32;
- compare to feed-forward convolutional network;
- try different input features, different numbers of LSTM layers, and different hidden layer sizes.

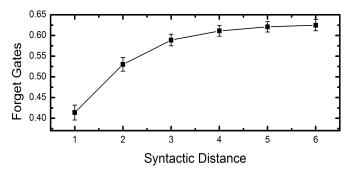

## Results for CoNLL-2005 Dataset

Embedding	d	ctx-p	$m_r$	h	F1(dev)	F1
Random	1	1	n	32	47.88	49.44
Random	1	5	n	32	54.63	56.85
Random	1	5	у	32	57.13	58.71
Wikipedia	1	5	у	32	64.48	65.11
Wikipedia	2	5	У	32	72.72	72.56
Wikipedia	4	5	У	32	75.08	75.74
Wikipedia	6	5	У	32	76.94	78.02
Wikipedia	8	5	У	32	77.50	78.28
Wikipedia	8	5	У	64	77.69	79.46
Wikipedia	8	5	у	128	79.10	80.28
Wikipedia	8	5	У	128	79.55	81.07

d: number of LSTM layers; ctx-p: context length;  $m_r$ : region mark used or not; h: hidden layer size. Last row with fine tuning.

### What the Model Learns

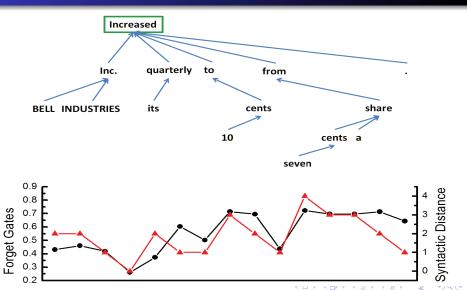

Model learns "syntax": it associates argument and predicate words using the forget gate:

Syntactic distance is the number of edges between argument and predicate in the dependency tree.

# What the Model Learns

# Summary

- Semantic role labeling means identifying the arguments (frame elements) that participate in a prototypical situation (frame) and labeling them with their roles;
- this provides a shallow semantic analysis that can benefit various NLP applications;
- SRL transitionally consists of parsing, frame element matching, feature extraction, classification;
- but it can also regarded as a sequence labeling task;
- Zhou and Xu (2015) use a deep bi-directional LSTM trained on embeddings to do SRL;
- no parsing needed, no handcrafted features;
- forget gates help the net to learn syntactic dependencies.
